## 1 Component Name

RFChannelEmulator

## 2 Component Processing Summary

The RFChannelEmulator component adds noise to the baseband MSK signal before demodulation to emulate the effects of a noisy channel in wireless communications links.

## 3 Where used

The RFChannelEmulator exists between the MSK modulator and demodulator components in all FM3TR waveforms.

## 4 Data Input and Output Ports

The RFChannelEmulator component has one uses and one provides data port. Both the input (RF\_In) and output (RF\_Out) data ports operate on a sequence of signed complex short integers.

## 5 Control Interfaces

The RFChannelEmulator component inherits the control interfaces from CF::Resource.

## 6 Component SCA Properties

Aside from the DLL execparams, the RFChannelEmulator has one SCA configure property, “Noise\_Power\_dB” which sets the amount of noise injected on the transmitted signal before demodulation.

## 7 Component Attributes/Key Variables

Below is a list of several key variables to the RF channel emulator component with a brief description of their purpose.

m_sigma	Noise variance.
---------	-----------------

## 8 Processing Details

The RFChannelEmulator provides two distributions for injecting noise on the transmitted signal: Gaussian and uniform. Once the noise is generated, it is added to the incoming signal and the result is passed to the demodulator.

### 8.1 Method: ComplexAWGN()

The *ComplexAWGN()* method generates a sequence of complex additive white gaussian noise (AWGN) samples. This is accomplished by summing  $N$  Bernoulli trials to generate

binomial random variable. This is a simple way to approximate a Gaussian random variable, although it is not as efficient as other methods.

## **8.2 Method: ComplexAWUN()**

The *ComplexAWUN()* method generates a sequence of complex additive uniform noise (AWUN) samples using the standard *rand()* function.
